Background: The aim of this study was to investigate the role of pre-treatment aspartate aminotransferase-lynphocyte ratio (ALRI) as a predictor of prognosis and treatment efficacy in patients with metastatic colorectal cancer (mCRC) enrolled in the prospective multicenter randomized ITACa (Italian Trial in Advanced Colorectal Cancer) trial to receive first-line chemotherapy (CT) + bevacizumab (B) or CT alone.

Patients and methods: Patients randomly received CT+B or CT alone as first-line therapy. CT consisted of either FOLFOX4 or FOLFIRI at the clinician's discretion.

Results: Out of the 284 patients enrolled, increased ALRI levels were associated with shorter PFS and OS (p < 0.0001). At baseline, median PFS was 10.3 months (95% CI 9.4–12.0) and 8.0 months (95 % CI 6.8–8.9), and median OS was 25.2 months (95 % CI 21.3–30.2) and 18.8 months (95 % CI 16.6–21.7) for patients with low (<14) and high (\geq 14) ALRI levels, respectively (HR 1.43, 95% CI 1.12–1.82, p=0.004; HR=1.51, 95% CI 1.17–1.96, p<0.001). Interaction tests on ALRI levels and treatment efficacy in the CT+B and the CT groups were statistically significant for PFS (p=0.0003), but not for OS (p=0.228).

Conclusion: Our results indicate that ALRI is a good prognostic and predictive marker for mCRC patients candidate for CT+B.

Keywords: metastatic colorectal cancer, bevacizumab, first line, prognosis, aspartate aminotransferase-lymphocyte ratio index, clinical outcome, rectal cancer

Introduction

Colorectal cancer (CRC) is the third most common cause of death from cancer in Western Europe and North America.¹

Literature has shown the relationship between systemic chronic inflammation and various types of cancer, including CRC,² as the activation of the inflammatory cascade by malignant tumors leads to apoptosis inhibition and angiogenesis promotion, eventually causing tumor genesis, proliferation, and metastasis.^{3,4}

In clinical practice, physicians commonly test the liver enzyme aspartate aminotransferase (AST), without evidence of any correlation with the response to bevacizumab (B).

To our knowledge, no population-based study has yet been conducted on the prognostic value of baseline AST-lymphocyte ratio index (ALRI) in predicting progression-free survival (PFS) in CRC patients treated with B. We think that the ALRI is an important parameter that provides data after combining the inflammatory state with a hepatic index.

Dovepress

We investigated the prognostic and predictive roles of baseline ALRI in metastatic CRC (mCRC) patients treated with first-line chemotherapy (CT)+B or CT alone in the Phase III prospective multicenter randomized ITACa trial (Italian Trial in Advanced Colorectal Cancer; EudraCT no 2007-004539-44 and on <u>ClinicalTrials.gov</u> NCT01878422).⁵

Patients and methods The ITACa trial

Patients randomly received CT+B or CT alone as first-line therapy. CT consisted of either FOLFOX4 (a 2-hour infusion of 85 mg/m² oxaliplatin on day 1 and a 2-hour infusion of 100 mg/m² leucovorin followed by 400 mg/m² bolus 5-FU and a 22-hour infusion of 600 mg/m² 5-FU on days 1–2 every 2 weeks) or FOLFIRI (a 2-hour infusion of 100 mg/m² leucovorin followed by 400 mg/m² bolus 5-FU and a 22-hour infusion of 600 mg/m² bolus 5-FU and a 22-hour infusion of 600 mg/m² bolus 5-FU and a 22-hour infusion of 600 mg/m² bolus 5-FU and a 22-hour infusion of 600 mg/m² 5-FU on days 1–2 every 2 weeks with the addition of a 90-minute infusion of 180 mg/m² irinotecan on day 1) at the clinician's discretion. A 30–90-minute intravenous infusion of 5 mg/kg B was administered on day 1 of each 2-week cycle.

Treatment continued until either progressive disease (PD) or unacceptable toxicity or withdrawal of consent. Tumor assessment was performed before the start of treatment and repeated every 8 weeks until PD. Responses were defined according to the Response Evaluation Criteria in Solid Tumors guidelines (per investigator assessment). The National Cancer Institute Common Toxicity Criteria were used for evaluating adverse events.

The ITACa trial was approved by the local ethics committee (Comitato Etico Area Vasta Romagna) on September 19, 2007 and registered in our National Clinical Trials Observatory (Osservatorio delle Sperimentazioni Cliniche) and in the European Clinical Trials Database (EudraCT no 2007-004539-44) before patient recruitment began. Registration on ClinicalTrials.gov (NCT01878422) was not mandatory but was carried out at a later date (June 7, 2013). All patients provided written informed consent. The study was carried out in accordance with the Declaration of Helsinki under good clinical practice conditions and after full approval of the ethics committees of all participating centers (Comitato Etico Area Vasta Romagna e IRST, Comitato Etico Provinciale di Modena, Comitato Etico AUSL di Piacenza, Comitato Etico Interaziendale AOU "Maggiore della Carità" di Novara, Comitato Etico Interaziendale dell'A.S.O. Santa Croce e Carle di Cuneo, Comitato Etico della Provincia di Modena, Comitato Etico della Provincia di Ferrara, Comitato Etico Unico per la Provincia di Parma, Comitato Etico

Indipendente Azienda USL di Bologna, Comitato Etico della ASL LE di Lecce, Comitato Etico Provinciale di Belluno per la Sperimentazione Clinica).

Statistical analysis

PFS and overall survival (OS) were, respectively, the primary and one of the secondary endpoints of the ITACa study. Information on AST and lymphocyte counts from blood tests carried out at baseline (before systemic treatment) was collected subsequently for the purpose of this post hoc analysis. ALRI was calculated as AST/lymphocyte count. The aim of this analysis was to evaluate the association between baseline ALRI levels and PFS and OS in the intent-to-treat population.

PFS was defined as the time from the date of random assignment to the date of either first documentation of PD, or last tumor evaluation, or death from any cause. Patients undergoing curative metastasectomy were censored at the date of surgery. OS was defined as the time from the date of random assignment to the date of death or last follow-up visit. PFS and OS were estimated by Kaplan-Meier method and curves were compared using the log rank test. Cox regression model was used to estimate HRs, their 2-sided 95% CI, and HR adjusted by center, baseline characteristics (gender, age, Eastern Cooperative Oncology Group performance status [ECOG PS], KRAS status, and tumor localization), CT regimen, and ITACa treatment. Cox regression model was also used to evaluate the effect on PFS and OS of the interaction between ALRI levels and treatment, including ALRI levels, treatment, and treatment-by-ALRI levels. X-tile 3.6.1 software (Yale University, New Haven, CT, USA) was used for bioinformatics analysis of baseline data to determine the cutoff value for pretreatment levels of ALRI. ALRI \geq 14 was considered as a high level.

Patient characteristics were compared with χ^2 test, and median values were compared using nonparametric ranking test (median test). All *p*-values were based on 2-sided testing. Statistical analyses were performed using SAS statistical software version 9.4 (SAS Inc., Cary, NC, USA).

Results

Patient characteristics

Between November 14, 2007 and March 6, 2012, 284 patients diagnosed with CRC were available for baseline AST and lymphocyte analysis (Figure 1); the study sample included 170 (59.8%) males and 114 (40.2%) females with a median age at diagnosis of 66 years (range 33–83). Median follow-up

Figure I Flow chart of the study.

Abbreviation: ALRI, aspartate aminotransferase-lymphocyte ratio index.

was 36 months (range 1–65). Overall, median PFS was 9.1 (95% CI 8.4–9.8) and median OS was 21.4 months (95% CI 19.9–24.5). The 2 groups of patients were comparable with regard to age, gender, tumor localization, stage at diagnosis, KRAS status, and ITACa treatment. A considerable proportion of patients with high ALRI had performance status 1–2.

ALRI values and clinical outcome in all patients

Considering ALRI as a continuous variable, we observed that increased ALRI levels were associated with decreased PFS (HR 1.02, 95% CI 1.01–1.02, p<0.0001) and OS (HR 1.02, 95% CI 1.02–1.03, p<0.0001).

The 2 groups of patients were comparable for all the major clinical characteristics investigated, except for EOCG and CT regimen (Table 1).

At baseline, median PFS was 10.3 months (95% CI 9.4–12.0) and 8.0 months (95% CI 6.8–8.9) for patients with low (<14) and high (\geq 14) ALRI levels, respectively (HR 1.43, 95% CI 1.12–1.82, *p*=0.004) (Figure 2A). Median OS was 25.5 months (95% CI 21.3–30.2) and 18.8 months (95% CI 16.6–21.7) for patients with low and high baseline ALRI levels, respectively (HR 1.51, 95% CI 1.17–1.96, *p*<0.001) (Figure 2B). ALRI, AST, and lymphocyte values were associated with different toxicities (Table 2).

Following adjustment for clinical covariates (age, gender, ECOG, tumor localization, CT regimen, KRAS status, ITACa treatment, and LDH level and liver metastasis), multivariate analysis confirmed ALRI as an independent prognostic factor for predicting PFS (HR 1.35, 95% CI 1.02–1.79, p=0.034) and OS (HR 1.35, 95% CI 1.01–1.83 p=0.048) (Table 3).

ALRI values and clinical outcome in patients treated with CT+B

Considering ALRI as a continuous variable, we observed also in patients undergoing CT+B that increased ALRI levels were associated with decreased PFS (HR 1.01, 95% CI 1.01–1.02, *p*=0.001) and OS (HR 1.02, 95% CI 1.01–1.03, *p*<0.0001).

At baseline, median PFS was 11.3 months (95% CI 9.1–13.4) and 9.2 months (95% CI 6.8–11.3) for patients with low and high ALRI levels, respectively (p=0.304; HR 1.20, 95% CI 0.85–1.69, p=0.304) (Figure 3A). On the other hand, median OS was 22.7 and 15.9 months for patients with low and high baseline ALRI, respectively (HR 1.36, 95% CI 0.95–1.96, p=0.095) (Figure 3B).

ALRI values and clinical outcome in patients treated with CT alone

Considering ALRI as a continuous variable, we observed also in patients undergoing CT alone that increased ALRI levels were associated with decreased PFS (HR 1.04, 95% CI 1.03–1.05, p<0.0001) and OS (HR 1.03, 95% CI 1.02–1.04, p<0.0001).

At baseline, median PFS was 10.0 months (95% CI 9.0–11.8) and 7.0 months (95% CI 5.9–8.4) for patients with low and high ALRI levels, respectively (p=0.002; HR 1.71, 95% CI 1.22–2.41, p=0.002) (Figure 3C). Median OS was 27.1 and 20.2 months for patients with low and high baseline ALRI levels, respectively (p=0.007; HR 1.64, 95% CI 1.14–2.36, p=0.007) (Figure 3D).

Interaction tests on ALRI levels and treatment efficacy in the CT+B and CT only groups were statistically significant for PFS (p=0.0003) but not for OS (p=0.228).

Figure 4 shows the Kaplan–Meier curves of PFS of patients treated with CT+B and CT alone with respect to ALRI levels.

Figure 2 Kaplan-Meier curves of PFS (A), OS (B).

Abbreviations: ALRI, aspartate aminotransferase-lymphocyte ratio index; PFS, progression-free survival; OS, overall survival.

Abbreviations: ALRI, aspartate aminotransferase-lymphocyte ratio index; CT, chemotherapy; ECOG PS, Eastern Cooperative Oncology Group performance status; ITACa, Italian Trial in Advanced Colorectal Cancer; LDH, lactate dehydrogenase; PFS, progression-free survival; OS, overall survival; UNL, upper normal limit.

Figure 3 Kaplan–Meier curves of PFS (**A**) and OS (**B**) of patients treated with CT+B, Kaplan–Meier curves of PFS (**C**) and OS (**D**) in patients treated with CT. Abbreviations: ALRI, aspartate aminotransferase-lymphocyte ratio index; B, bevacizumab; CT, chemotherapy; OS, overall survival; PFS, progression-free survival.

Figure 4 Kaplan–Meier curves of PFS of patients treated with CT+B and CT on the basis of ALRI levels.

Abbreviations: ALRI, aspartate aminotransferase-lymphocyte ratio index; B, bevacizumab; CT, chemotherapy; PFS, progression-free survival.

AST and lymphocyte values and clinical outcome in all patients

Considering ALRI as a continuous variable, we observed that increased AST levels were associated with decreased PFS (HR 1.01, 95% CI 1.01–1.02, p=0.0002) and OS (HR 1.02, 95% CI 1.01–1.02, p<0.0001). Among basal characteristics, we observed that AST levels were higher in patients with liver disease (Table 4).

Considering lymphocyte as a continuous variable, we observed that increased lymphocyte levels were associated with decreased PFS (HR 0.84, 95% CI 0.72–0.99, p=0.036), but not OS (HR 0.91, 95% CI 0.77–1.06, p=0.214).

Discussion

Our study showed that high levels of ALRI at baseline were associated with shorter PFS and OS than low ALRI levels. To our knowledge, our study is the first to have assessed the prognostic value of ALRI in patients with CRC, potentially representing a noninvasive predictor of prognosis for CRC patients. However, the cutoff value of ALRI in our report was different from what was previously reported in other diseases.^{6,7} ALRI was evaluated in particular in patients with hepatocellular carcinoma, as levels of AST are higher and lymphocyte levels are lower due to cirrhosis.

AST plays a role in the metabolism of amino acids in the liver, and thus its increase becomes a biochemical marker of liver failure.⁸ Lymphocytes play a role in the antitumor immune response, and their presence relates to a reduced risk of relapse in several situations.⁹ Increased serum AST may be a result of the progression of liver diseases, as intracellular AST is released when the hepatic parenchymal cells are injured. Conversely, decreased lymphocytes can reduce the antitumor immunity of the patients. For this reason, ALRI may be used for predicting response and OS.

B, a recombinant humanized monoclonal antibody directed against vascular endothelial growth factor, was found to improve survival in both first- and second-line settings when added to CT.¹⁰ There is no current validated clinical or biological factor that can predict response to B. A positive result to the interaction test indicates that the ALRI index may be predictive of B efficacy. We hypothesize that B may be capable of contrasting the negative predictive value of high baseline levels of ALRI. In fact, among patients with high ALRI levels, PFS was lower in those treated with CT alone than in those treated with CT+B.

With regard to toxicity, it is noteworthy that high values of ALRI and AST were mostly associated with a higher incidence of fatigue, probably as result of a greater amount of liver disease at baseline, which may induce higher chemorelated toxicity.

In conclusion, pretreatment levels of ALRI may constitute a marker of aggressiveness in CRC patients. Elevated ALRI levels prior to treatment seem to be indicators of poor prognosis.

Author contributions

The study was conceptualized and designed by Andrea Casadei Gardini. All authors assisted with collection and assembly of data. Andrea Casadei Gardini, Emanuela Scarpi, and Alessandro Passardi analyzed and interpreted the data.

Table 4 Liver disease and median value of AST

	Number of patients	AST median value (range)	p-values	Lymphocyte median value (range)	p-values	ALRI median value (range)	p-values
Overall			<0.0001		0.229		0.003
No liver disease +1 single liver lesion <5 cm	81	17 (9–117)		1.51 (0.56–10.40)		12.70 (1.35–80.15)	
Multiple lesions (including 1 liver) or 1 single hepatic lesion \ge 5 cm	203	23 (8–193)		1.62 (0.43–10.51)		15.20 (2.05–172.32)	

Abbreviations: ALRI, aspartate aminotransferase-lymphocyte ratio index; AST, aspartate aminotransferase.

All authors were involved in manuscript writing. All authors finally approved the manuscript. The corresponding author had the final responsibility to submit for publication. All authors contributed toward data analysis, drafting and critically revising the paper and agree to be accountable for all aspects of the work.

Acknowledgments

This trial was partially supported by the Italian Medicines Agency (Agenzia Italiana del Farmaco, AIFA – research grant no FARM6FJJAY). The study sponsor was involved neither in the study design nor in the collection, analysis, and interpretation of data. The study sponsor did not provide writing support for the report. All authors had full access to all the data in the study.

The authors would like to thank Cristiano Verna and Veronica Zanoni for editing the manuscript and Angela Ragazzini, Monia Dall'Agata (Meldola), Luigi Cavanna, Maria Angela Palladino, Camilla Di Nunzio, Claudia Biasini (Piacenza), Britt Rudnas, Barbara Venturini (Rimini), Caterina Accettura (Lecce), Giorgia Razzini (Carpi), Jody Corbelli, Alessandra Piancastelli (Faenza), Bernadette Vertogen, and Federica Zumaglini (Ravenna) for participating in this study.

The abstract of this paper was presented at the ESMO 2017 Conference as a poster presentation with interim findings. The poster's abstract was published in "Poster Abstracts" in *Annals of Oncology*: <u>https://academic.oup.com/annonc/article-abstract/28/suppl_6/mdx422.035/4583119?</u> redirectedFrom=fulltext.
